1 METHOD AND SYSTEM FOR  
2 DEVELOPING TRAFFIC MESSAGES

3 REFERENCE TO RELATED APPLICATION

4 The present application is related to the co-pending application entitled  
5 "METHOD AND SYSTEM FOR DEVELOPING TRAFFIC MESSAGES" filed on the  
6 same date herewith, Attorney Docket No. N0166US, the entire disclosure of which is  
7 incorporated by reference herein. The present application is also related to the co-  
8 pending application entitled "METHOD AND SYSTEM FOR DEVELOPING TRAFFIC  
9 MESSAGES" filed on the same date herewith, Attorney Docket No. N0173US, the entire  
10 disclosure of which is incorporated by reference herein. Additionally, the present  
11 application is related to the co-pending application entitled "METHOD AND SYSTEM  
12 FOR DEVELOPING TRAFFIC MESSAGES" filed on the same date herewith, Attorney  
13 Docket No. N0174US, the entire disclosure of which is incorporated by reference herein.

14  
15 BACKGROUND OF THE INVENTION

16 The present invention relates to a system and method for providing traffic data to  
17 mobile users, such as vehicles traveling on roads, and more particularly, the present  
18 invention relates to a system and method that develops traffic messages for broadcast.

19 In some metropolitan areas and countries, systems have been implemented that  
20 broadcast data messages that contain up-to-the-minute reports of traffic and road  
21 condition information. These systems broadcast the data messages on a continuous,  
22 periodic, or frequently occurring basis. Receivers installed in vehicles that travel in the  
23 region receive the data messages. The receivers decode the data messages and make the  
24 information in the messages available to the vehicle drivers.

25 The traffic data message broadcast systems have several advantages over radio  
26 stations simply broadcasting traffic reports. For example, with the traffic data message  
27 broadcasting systems, a driver can obtain the traffic information quickly. The driver does  
28 not have to wait until the radio station broadcasts a traffic report. Another advantage of

1 the traffic data message broadcast systems is that the driver does not have to listen to  
2 descriptions of traffic conditions for areas remote from his or her location. Another  
3 advantage of traffic data message broadcast systems is that more detailed and possibly  
4 more up-to-date information can be provided. In these types of systems, the data  
5 messages conform to one or more pre-established specifications or formats. The in-  
6 vehicle receivers decode the traffic data messages using the pre-established specifications  
7 or formats.

8 One system for broadcasting traffic and road condition information is the Radio  
9 Data System-Traffic Message Channel ("RDS-TMC"). The RDS-TMC system is used in  
10 some European countries. The RDS-TMC system broadcasts messages to vehicles using  
11 an FM station data channel. RDS-TMC messages are broadcast regularly or at varying  
12 intervals.

13 One challenge with broadcasting traffic and road condition messages is creating  
14 these messages. Traffic and road condition data may be collected from a variety of  
15 sources in a variety of different data formats. The traffic and road condition data must be  
16 assimilated and transformed into a group of messages that indicate relevant traffic and  
17 road conditions. Additionally, the broadcast bandwidth for the messages may be limited,  
18 so only a limited number of messages may be broadcast. Furthermore, the end user  
19 computing platform may only be able to handle a limited number of messages.  
20 Moreover, the end user computing platform may desire to select the traffic messages  
21 relevant to its present location.

22 Accordingly, it would be beneficial to have a way to collect traffic and road  
23 condition data, to develop a group of messages that indicate relevant traffic and road  
24 conditions for broadcast.

25

## 26 SUMMARY OF THE INVENTION

27 To address these and other objectives, the present invention comprises a method  
28 for developing traffic messages for transmission. Data indicating a plurality of traffic  
29 conditions are obtained. For each of the traffic conditions, the data provides a start  
30 location at which the traffic condition begins and an end location at which the traffic  
31 condition ends. For each of the traffic conditions, a road length from the start location to

1 the end location is determined. The traffic conditions are assigned a priority based upon  
2 the road lengths. The data indicating the traffic conditions are transmitted in the assigned  
3 priority as a plurality of traffic messages.

4 According to another aspect, the present invention comprises a method for  
5 developing traffic messages for transmission. Data indicating a plurality of traffic  
6 conditions are obtained. The traffic conditions are prioritized based upon considering at  
7 least one of: a road length affected by the traffic condition, a type of traffic condition, a  
8 road type on which the traffic condition is located, a priority location is located within the  
9 traffic condition, a direction of traffic affected by the traffic condition, a duration of the  
10 traffic condition and co-location or connection with another of the traffic conditions.

11

## 12 BRIEF DESCRIPTION OF THE DRAWINGS

13 Figure 1 is a diagram illustrating components of a traffic broadcast system in a  
14 geographic region.

15 Figure 2 is a block diagram illustrating components of the traffic broadcast system  
16 and one of the vehicles with an on-board navigation system, as shown in Figure 1.

17 Figure 3 is a block diagram illustrating the components of a central facility of the  
18 traffic broadcast system as shown in Figures 1 and 2.

19 Figure 4 is a flow chart illustrating the steps performed by the central facility  
20 illustrated in Figure 3.

21 Figure 5 is an example of a portion of a traffic location table illustrated in Figure  
22 3.

23 Figure 6 is a flow chart of the steps performed by the central facility to resolve the  
24 collected traffic and road condition data.

25 Figure 7 is a flow chart of the steps performed by the central facility to aggregate  
26 the traffic data.

27 Figure 8 is a diagram illustrating a road with traffic location codes and  
28 corresponding speed data.

29 Figure 9 is a flow chart of the steps performed by the central facility to prioritize  
30 the traffic and road condition data.

1        Figure 10 is a diagram illustrating data components included in one of the traffic  
2 messages.

3        Figure 11 is a flow chart of the steps performed by the central facility to format  
4 the traffic data into traffic messages.

5        Figure 12 illustrates formation of broadcast service areas within the geographic  
6 region of Figure 1.

7        Figure 13a is a diagram illustrating a traffic packet.

8        Figure 13b is a diagram illustrating a service provider message included in the  
9 traffic packet of Figure 13a.

10       Figure 13c is a diagram illustrating a traffic message included in the traffic packet  
11 of Figure 13a.

## 13       DETAILED DESCRIPTION OF THE 14       PRESENTLY PREFERRED EMBODIMENTS

### 15       I.       TRAFFIC INFORMATION BROADCAST SYSTEM - OVERVIEW

16       Figure 1 is a diagram illustrating a geographic region 10. The geographic region  
17 10 includes a road network 12 comprising numerous road segments 14 on which  
18 numerous vehicles 16 travel. The vehicles 16 may include cars, trucks, buses, bicycles,  
19 motorcycles, etc. The geographic region 10 may be a metropolitan area, such as the New  
20 York metropolitan area, the Chicago metropolitan area, or any other metropolitan area.  
21 Alternatively, the geographic region 10 may be a state, province, or country, such as  
22 California, Illinois, France, England, or Germany. Alternatively, the geographic region  
23 10 can be a combination of one or more metropolitan areas, states, countries and so on.

24       A traffic information broadcast system 20 broadcasts traffic messages 22  
25 regarding the traffic and road conditions on the road network 12 in the geographic region  
26 10. A traffic information provider 24 operates the traffic information broadcast system  
27 20. Some or all of the vehicles 16 include suitable equipment that enables them to  
28 receive the traffic messages 22 broadcast by the traffic information broadcast system 20.  
29 The traffic messages 22 may also be received and used in systems that are not installed in  
30 vehicles (e.g., "non-vehicles 18"). These non-vehicles 18 may include workstations,  
31 personal computers, personal digital assistants, networks, pagers, televisions, radio

1 receivers, telephones, and so on. The non-vehicles 18 that receive the traffic messages 22  
2 may obtain them in the same manner as the vehicles, i.e., by broadcast. Alternatively, the  
3 non-vehicles 18 may receive the traffic messages 22 by other means, such as over  
4 telephone lines, over the Internet, via cable, and so on. The systems in the vehicles 16 or  
5 in the non-vehicles 18 that receive the traffic messages 22 may include various different  
6 platforms as known to those skilled in the art.

7 Figure 2 shows diagrammatically the components of the traffic information  
8 broadcast system 20 and one of the vehicles 16 in Figure 1. The traffic information  
9 broadcast system 20 provides for collecting of data relating to traffic and road conditions,  
10 developing traffic messages from the collected data, and transmitting the traffic messages  
11 22 to the vehicles 16 and non-vehicles 18 in the region 10 on a regular and continuing  
12 basis.

13 The traffic information broadcast system 20 includes a central facility 26 operated  
14 by the traffic information provider 24. The central facility 26 includes equipment and  
15 programming 26(1) for collecting the data relating to traffic and road conditions in the  
16 region 10 from various sources or manual input. The central facility 26 also includes  
17 equipment and programming 26(2) for developing the traffic messages from the collected  
18 traffic and road condition data. Furthermore, the central facility 26 includes suitable  
19 equipment and programming 26(3) for broadcasting the traffic messages 22. To  
20 broadcast the traffic messages 22, the traffic information broadcast system 20 includes  
21 transmission equipment 28. The transmission equipment 28 may comprise one or more  
22 FM transmitters, including antennas, or other wireless transmitters. The transmission  
23 equipment 28 provides for broadcasting the traffic messages 22 throughout the region 10.  
24 The transmission equipment 28 may be part of the traffic information broadcast system  
25 20, or alternatively, the transmission equipment 28 may use equipment from other types  
26 of systems, such as cellular or paging systems, satellite radio, FM radio stations, and so  
27 on, to broadcast traffic messages 22 to the vehicles 16 and non-vehicles 18 in the region.  
28 In one embodiment, the central facility 26 transmits the traffic messages 22 to a  
29 broadcaster that broadcasts the traffic messages 22. (For purposes of this disclosure and  
30 the appended claims, the broadcasting of traffic messages is intended to include any form  
31 of transmission, including direct wireless transmission.)

1 Vehicles 16 and non-vehicles 18 in the region 10 have appropriate equipment for  
2 receiving the traffic messages 22. In one embodiment, installed in some of the vehicles  
3 16 are a navigation system 30 that can receive and use the traffic messages 22. As shown  
4 in Figure 2, the navigation system 30 is a combination of hardware and software  
5 components. In one embodiment, the navigation system 30 includes a processor 32, a  
6 drive 34 connected to the processor 32, and a non-volatile memory storage device 36 for  
7 storing navigation application software programs 38 and possibly other information. The  
8 processor 32 may be of any type used in navigation systems.

9 The navigation system 30 may also include a positioning system 40. The  
10 positioning system 40 may utilize GPS-type technology, a dead reckoning-type system,  
11 or combinations of these, or other systems, all of which are known in the art. The  
12 positioning system 40 may include suitable sensing devices that measure the traveling  
13 distance speed, direction, and so on, of the vehicle. The positioning system 40 may also  
14 include appropriate technology to obtain a GPS signal, in a manner that is known in the  
15 art. The positioning system 40 outputs a signal to the processor 32. The navigation  
16 application software program 38 that is run on the processor 32 may use the signal from  
17 the positioning system 40 to determine the location, direction, speed, etc., of the vehicle  
18 16.

19 Referring to Figure 2, the vehicle 16 includes a traffic message receiver 42. The  
20 receiver 42 may be a satellite radio or FM receiver tuned to the appropriate frequency  
21 used by the traffic broadcast information system 20 to broadcast the traffic messages 22.  
22 The receiver 42 receives the traffic messages 22 from the traffic data provider 24. (In an  
23 alternative in which the traffic messages are sent by a direct wireless transmission, such  
24 as via a cellular wireless transmission, the receiver 42 in the vehicle 16 may be similar or  
25 identical to a cellular telephone.) The receiver 42 provides an output to the processor 32  
26 so that appropriate programming in the navigation system 30 can utilize the traffic  
27 messages 22 broadcast by the traffic broadcast system 20 when performing navigation  
28 functions, as described more fully below.

29 The navigation system 30 also includes a user interface 44 that allows the end  
30 user (e.g., the driver or passengers) to input information into the navigation system. This

1 input information may include a request to use the navigation features of the navigation  
2 system 30.

3 The navigation system 30 uses a geographic database 46 stored on a storage  
4 medium 48. In this embodiment, the storage medium 48 is installed in the drive 34 so  
5 that the geographic database 46 can be read and used by the navigation system 40. In one  
6 embodiment, the geographic data 46 may be a geographic database published by  
7 Navigation Technologies of Chicago, Illinois. The storage medium 48 and the  
8 geographic database 46 do not have to be physically provided at the location of the  
9 navigation system 30. In alternative embodiments, the storage medium 48, upon which  
10 some or all of the geographic data 46 are stored, may be located remotely from the rest of  
11 the navigation system 30 and portions of the geographic data provided via a  
12 communications link, as needed.

13 In one exemplary type of system, the navigation application software program 38  
14 is loaded from the non-volatile memory 36 into a RAM 50 associated with the processor  
15 32 in order to operate the navigation system 30. The processor 32 also receives input  
16 from the user interface 44. The input may include a request for navigation information.  
17 The navigation system 30 uses the geographic database 46 stored on the storage medium  
18 48, possibly in conjunction with the outputs from the positioning system 40 and the  
19 receiver 42, to provide various navigation features and functions. The navigation  
20 application software program 38 may include separate applications (or subprograms) that  
21 provide these various navigation features and functions. These functions and features  
22 may include route calculation 52 (wherein a route to a destination identified by the end-  
23 user is determined), route guidance 54 (wherein detailed directions are provided for  
24 reaching a desired destination), map display 56, and vehicle positioning 58 (e.g., map  
25 matching).

26 Also included in the programming 38 on the navigation system is location  
27 referencing programming 60. The location referencing programming 60 facilitates using  
28 data contained in the traffic messages 22 when performing navigation functions. A  
29 method for providing this feature is disclosed in U.S. Patent No. 6,438,561, entitled  
30 "METHOD AND SYSTEM FOR USING REAL-TIME TRAFFIC BROADCASTS  
31 WITH NAVIGATION SYSTEMS", the entire disclosure of which is incorporated by

1 reference herein. U.S. Patent No. 6,438,561 discloses a method and system in which  
2 location reference codes used in traffic messages 22 are related to geographic data used  
3 by the navigation system 30 thereby enabling navigation system 30 to use the information  
4 contained in traffic message broadcasts. Using data from broadcast traffic messages 22  
5 together with a geographic database 46 allows the navigation system 30 to provide route  
6 calculation that considers up-to-the-minute traffic and road conditions when determining  
7 a route to a desired destination.

8 Other functions and programming 62 may be included in the navigation system  
9 30. The navigation application program 38 may be written in a suitable computer  
10 programming language such as C, although other programming languages, such as C++  
11 or Java, are also suitable. All of the components described above may be conventional  
12 (or other than conventional) and the manufacture and use of these components are known  
13 to those of skill in the art.

14

## 15 II. METHOD AND SYSTEM FOR DEVELOPING TRAFFIC MESSAGES

### 16 A. General Overview

17 The traffic information broadcast system 20 provides for collecting of data  
18 indicating traffic and road conditions, developing traffic messages from the collected  
19 data, and transmitting the traffic messages 22 to the vehicles 16 and non-vehicles 18 in  
20 the region 10 on a regular and continuing basis. The traffic information broadcast system  
21 20 includes the central facility 26 that develops traffic messages 22. The central facility  
22 26 includes suitable equipment and programming 26(2) for developing the traffic  
23 messages 22 as illustrated in Figure 3. The suitable equipment and programming 26(2)  
24 for developing the traffic messages 22 is a combination of hardware and software  
25 components. In one embodiment, the central facility 26 includes a computing platform  
26 70, such as a personal computer, having a processor 72, RAM 74, user interface 76,  
27 communication system 78 and non-volatile storage device 80 for storing a traffic message  
28 program 82 that develops the traffic messages 22. An operator may use the user interface  
29 76 to manually enter and edit traffic information. The central facility 26 also includes a  
30 geographic database 84 containing geographic data representing the road network 12 of

1 the geographic region 10. In one embodiment, the geographic database 84 may contain  
2 the geographic data published by Navigation Technologies of Chicago, Illinois.

3 Figure 4 illustrates the steps performed by the traffic message program 82 of the  
4 central facility 26 to develop the traffic messages 22. At step 86, the central facility 26  
5 collects traffic and road condition data from a variety of sources with a collection  
6 subprogram 88. Because the central facility 26 may collect traffic and road condition  
7 data from a variety of sources, the collected traffic and road condition data may be in a  
8 variety of forms. Thus, at step 90, the central facility 26 converts the collected data into a  
9 unified data format representing traffic and road conditions at identified locations along  
10 the road network 12 with a conversion subprogram 92. In one embodiment, the central  
11 facility 26 converts the collected data into a set of traffic flow data and a set of traffic  
12 incident data, as described more fully below in conjunction with Figure 6.

13 Because the traffic flow data may contain indications of traffic flow speeds at  
14 many identified locations along the same road or connected road segments 14 of the road  
15 network 12, at step 94, the central facility 26 aggregates traffic flow data representing  
16 contiguous locations having below normal flow conditions with an aggregation  
17 subprogram 96 into a set of aggregated traffic flow data, as described more fully below in  
18 conjunction with Figures 7 and 8. The aggregated traffic flow data provides a model of  
19 the traffic flow conditions as would be perceived by a driver traveling along the road.

20 Because only a limited number of traffic messages may be broadcasted or handled  
21 by the navigation system 30, at step 98, the central facility 26 prioritizes the aggregated  
22 traffic flow data and traffic incident data with a prioritization subprogram 100 into a set  
23 of prioritized traffic data, as described more fully below in conjunction with Figure 9.

24 At step 102, the central facility 26 formats the prioritized traffic data into traffic  
25 messages 22 with a formatting subprogram 104, as described more fully below in  
26 conjunction with Figures 10, 11 and 12. After any necessary formatting into traffic  
27 messages 22, the central facility 26 distributes the traffic messages 22 for broadcast at  
28 step 106 with a distribution subprogram 108, as described more fully below in  
29 conjunction with Figures 13a, 13b and 13c.

30

31

1           B.       Traffic Location Tables

2           The central facility 26 includes traffic location tables 110 stored on non-volatile  
3 storage device 80. The traffic information provider 24 has developed the traffic location  
4 tables 110 to identify locations on the road network 12 for which traffic messages 22 may  
5 be developed. In one embodiment, the traffic location tables 110 are designed to be  
6 consistent with the RDS-TMS protocol.

7           Figure 5 illustrates an example of a portion 112 of one of the traffic location  
8 tables 110. The traffic location table 112 includes a table identification number ("Table  
9 ID") 114 that identifies the table. In one embodiment, the table identification number is a  
10 two-digit number, such as 06, uniquely identifying the traffic location table. The traffic  
11 location table 112 also includes a location identification code column ("Location ID")  
12 116. In one embodiment, the location identification code is a five-digit number, such as  
13 05529, that uniquely identifies a location on the road network 12.

14           The traffic location table 112 includes a location type column 118. In one  
15 embodiment, locations are of three types: area ("A6"), linear ("L1"), and point ("P1").  
16 Area is a predefined portion of the geographic region 10, such as a partition on a county  
17 boundary or metropolitan area, for example "San Diego Metro." Linear ("L1") is a pre-  
18 defined section of road or entire road, such as a portion of a highway. Point ("P1") is a  
19 pre-defined location along a road, such as a ramp intersection, a road junction, a  
20 tollbooth, a bridge/tunnel, a rest area, beginning/end of a road, administrative level or  
21 boundary.

22           The traffic location table 112 also includes a road number column 120. In one  
23 embodiment, the road number 120 is an alphanumeric representation of the road number  
24 of the road or highway, such as "I-5." Additionally, the traffic location table 112  
25 includes a road name column 122. In one embodiment, the road name 122 is an  
26 alphanumeric representation of the road name of the road or highway, such as "Lake  
27 Shore Drive."

28           Furthermore, the traffic location table 112 includes a first name column 124. For  
29 area locations, the first name is a name of the area. For linear locations, the first name is  
30 the direction of travel toward the negative end of the linear. In one embodiment, linear  
31 locations have pre-defined directions with a positive direction from the southernmost

1 point location to the northernmost point location or from the western most point location  
2 to the eastern most point location (other directions are also possible). For point locations,  
3 the first name is the location name, such as the junction name. The traffic location table  
4 112 also includes a second name column 126. For area locations and point locations, the  
5 second name is not populated. For linear locations, the second name is the direction of  
6 travel toward the positive end of the linear.

7         Additionally, the traffic location table 112 includes an area reference column 128.  
8 The area reference contains the area identification code in which the linear location and  
9 point locations belong. The traffic location table 112 also includes a linear reference  
10 column 130. The linear reference contains the linear identification code of which the  
11 point locations belong.

12         Furthermore, the traffic location table 112 includes a negative offset column 132  
13 that contains the location identification code of the previous location. For point locations,  
14 the negative offset is the location identification code of the previous point location. As  
15 described above, linear locations have pre-defined directions with a positive direction  
16 from the southernmost point location to the northernmost point location or from the  
17 western most point location to the eastern most point location. Thus, the negative offset  
18 is the previous point location in the negative direction. The traffic location table 112  
19 includes a positive offset column 132 that contains the location identification code of the  
20 next location. For point locations, the positive offset is the location identification code of  
21 the next point location in the positive direction.

22         Moreover, the traffic location table 112 includes a latitude column 136 and a  
23 longitude column 138. For point locations, the latitude and longitude location value for a  
24 point at the point location is provided.

25         In one embodiment, the traffic information provider 24 has location tables 110 for  
26 each country. A country code associated with a set of location tables 110 identifies the  
27 country represented by the tables.

28         Figure 5 and the above description illustrate one example of the traffic location  
29 tables 110. In alternative embodiments, the traffic location table 110 may include  
30 different elements or columns. Additionally, the traffic location table may have different  
31 formats than illustrated in Figure 5.

### C. Data Collection

As illustrated in Figure 4, the central facility 26 collects traffic and road condition data from a variety of sources at step 86. Generally, the collected traffic data comprises a location description and an event description of a traffic or road condition. The location description identifies a location or locations along the road network affected by the traffic or road condition. The event description identifies a type of traffic or road condition. The collected traffic data may also include a duration description. The duration description identifies when the traffic or road condition is expected to return to normal or change.

In one embodiment, the central facility 26 may receive traffic and road condition data from a commercial traffic supplier 140. The commercial traffic supplier 140 may provide traffic data indicating incidents, such as accidents, on the road network 12 in the geographic region 10. Additionally, the commercial traffic supplier 140 may provide traffic data indicating traffic speeds associated with certain locations on road network 12.

In one embodiment, the central facility 26 receives traffic data from the commercial traffic supplier 140 representing traffic speeds in a format illustrated in Table I or other formats.

**Table I**

Code	Direction	2:00	2:15	2:30	2:45	3:00	3:15	3:30	3:45
1234	Positive	50	55	55	50	55	50	50	50
1234	Negative	35	40	40	50	50	40	35	40
2345	Positive	40	35	30	30	35	40	50	55
2345	Negative	50	50	35	35	40	50	50	35

As shown in Table 1, the data indicating traffic speeds provides a location reference code identifying traffic locations. Location reference codes ("Code") refer to specific locations that are spaced apart from each other along a road. In one embodiment, the location reference codes may correspond to location identification numbers for point locations used in the traffic location table 112. For example, the location reference code includes a country code, a location table identification number and a point location

1 identification code. In an alternative embodiment, the location reference codes do not  
2 correspond to the location codes used in the traffic location table 112.

3 As shown in Table I, the data indicating traffic speeds also provides a direction of  
4 traffic flow as either "Positive" or "Negative." The "Positive" direction refers to a  
5 predetermined direction along a road specified by a positive offset and specified by the  
6 next traffic location code on the road. The "Negative" direction refers to a predetermined  
7 direction along a road specified by a negative offset and specified by the previous traffic  
8 location code on the road.

9 The data also includes traffic speeds for the location on the road network 12  
10 identified by the location reference code. As shown in Table I, the commercial traffic  
11 supplier 140 provides traffic speeds in fifteen-minute increments of time for each of the  
12 listed location reference codes. The speed data indicates the traffic speeds for the past  
13 half hour, the current traffic speeds and predicted traffic speeds. For the illustration of  
14 Table 1, the time at which the commercial traffic supplier 140 sent the data to the central  
15 facility 26 was approximately 2:30. In an alternative embodiment, the commercial traffic  
16 supplier 140 may provide congestion levels rather than the traffic speeds. Additionally,  
17 in an alternative embodiment, the commercial traffic supplier 140 may provide traffic  
18 speeds or congestion levels in different increments of time than the above fifteen-minute  
19 increments of time.

20 In addition to receiving data indicating traffic speeds at locations along the road  
21 network 12, the central facility 26 receives traffic data representing traffic incidents from  
22 the commercial traffic supplier 140 in a format illustrated in Table II or other formats.

23 Table II

Start Code	End Code	Start dir	End dir	End time	Event code
1234	1245	Positive	Positive	2:00 1/1/03	401
2345	2342	Negative	Negative	1:00 1/1/03	141

24

25 As shown in Table II, the data indicating traffic incidents provides a start location  
26 reference code and an end location reference code identifying a beginning location and an  
27 ending location of the incident on the road network 12. The start and end location  
28 reference codes refer to specific locations that are spaced apart from each other along a

1 road. In one embodiment, the location reference codes may correspond to point location  
2 identification codes used in the traffic location table 112. For example, the location  
3 reference code includes a country code, a location table identification number and a point  
4 location identification code. In an alternative embodiment, the location reference codes  
5 do not correspond to the location identification codes used in the traffic location table  
6 112.

7 As shown in Table II, the data indicating traffic incidents also provides a direction  
8 of traffic flow at the beginning and ending location of the incident as either "Positive" or  
9 "Negative." The "Positive" direction refers to a predetermined direction along a road  
10 specified by a positive offset and specified by the next traffic location code on the road.  
11 The "Negative" direction refers to a predetermined direction along a road specified by a  
12 negative offset and specified by the previous traffic location code on the road.

13 The data indicating traffic incidents may include a time and date at which the  
14 traffic incident is expected to end and traffic is expected to return to normal conditions.  
15 Moreover, the data includes an event code that describes the traffic incident. The event  
16 code may conform to a standard format such, as ALERT-C, or code that may be readily  
17 mapped to a standard format. For example, the event codes may indicate an accident,  
18 lane closures, lane restrictions, traffic restrictions, exit restrictions, carriageway  
19 restrictions, road works, obstruction hazards, road conditions, activities, dangerous  
20 vehicle and traffic equipment status.

21 The central facility 26 may also receive traffic and road condition data from a  
22 road authority 142, such as the Illinois Department of Transportation or other such  
23 organization. The road authority 142 may provide traffic data indicating traffic incidents  
24 and road conditions at locations along the road network 12. The traffic incidents and  
25 road conditions reported by the road authority may include accidents, delays, traffic  
26 backups, traffic congestion, construction activities, lane restrictions, traffic restrictions,  
27 exit restrictions, carriageway restrictions, road works, obstruction hazards, road  
28 conditions, dangerous vehicle and traffic equipment status or any other information  
29 regarding the road network 12. In one embodiment, the central facility 26 receives traffic  
30 data representing traffic incidents and road conditions from the road authority 142 in a  
31 format illustrated in Table III or other formats.

Table III

Main Road	Start Cross Road	End Cross Road	Direction	Duration	Event Type
I-5	Camino De La Plaza	I-805	South Bound (-)	2 hours	Left Lane Closed
CA-15	Main St	I-5	South Bound (-)	30 minutes	Heavy Congestion
I-5	Camino De La Plaza	Camino De La Plaza	South Bound (-)	2 hours	Debris on Road

As shown in Table III, the data indicating traffic incidents and road conditions provide descriptive information, such as a name, number or other description, of a road on which the incident or condition exists ("Main Road"). Additionally, the data includes descriptive information of a cross road or other point along the road at which the incident or condition begins ("Start Cross Road") and descriptive information of a cross road or other point along the road at which the incident or conditions ends ("End Cross Road"). The data also includes a direction of traffic along the road that is affected by the incident or condition. Furthermore, the data includes a duration indicating when the incident or condition will end. Moreover, the data includes a description of the incident or condition. In an alternative embodiment, the data may comprise a textual description, a severity type, a city name, and any other information.

The central facility 26 may also receive traffic and road condition data from sensors 144 located in, near or above locations along the road network 12. The sensors 144 may include equipment and programming, such as various communications links (including wireless links), receivers, data storage devices, programming that save the collected data, programming that logs data collection times and locations, programming that analyzes the data to determine traffic speeds and so on. In one embodiment, the sensors 144 collect data regarding traffic speeds at certain locations along the road network 12. The sensors 76 may include vehicle counting devices, video cameras, radar and any other sensor. In one embodiment, the central facility 26 receives the traffic data from the sensors 144 in a format illustrated in Table IV or other formats.

Table IV

Sensor ID	Location Code	Direction	Speed
0016	6789	Positive	35
0034	8912	Negative	40

2

3 As shown in Table IV, the data indicating traffic data provides a sensor identification  
4 number and a location reference code. Location reference codes ("Code") refer to  
5 specific locations that are spaced apart from each other along a road. In one embodiment,  
6 the location reference codes may correspond to point location identification codes used in  
7 the traffic location table 112. For example, the location reference code includes a country  
8 code, a location table identification number and a point location identification code. In  
9 an alternative embodiment, the location reference codes do not correspond to the location  
10 codes used in the traffic location table 112.

11 As shown in Table IV, the data indicating traffic speeds also provides a direction  
12 of traffic flow as either "Positive" or "Negative." The "Positive" direction refers to a  
13 predetermined direction along a road specified by a positive offset and specified by the  
14 next traffic location code on the road. The "Negative" direction refers to a predetermined  
15 direction along a road specified by a negative offset and specified by the previous traffic  
16 location code on the road. The data from the sensors 144 also includes current traffic  
17 speeds for the location on the road network 12 identified by the location reference code.

18 The central facility 26 may also receive traffic and road condition data from probe  
19 vehicles 146 traveling along the road network 12. A probe vehicle 146 is a vehicle that  
20 collects road-related data while it is being used for purposes unrelated to the collection of  
21 road-related data. For example, a probe vehicle is operated for ordinary, everyday  
22 purposes, such as commuting, leisure or business. A member of the public may operate  
23 the probe vehicle or alternatively a commercial enterprise or government entity may  
24 operate the probe vehicle. Each of the probe vehicles 146 may wirelessly communicate  
25 with the central facility 26 to provide data indicating a location of the vehicle and a  
26 speed. Analyzing data from numerous probe vehicles traveling the road network 12  
27 provides an indication of traffic conditions on the road network 12. In one embodiment,

1 the central facility 26 receives traffic data from the probe vehicles 78 in a format  
 2 illustrated by Table V or other formats.

3 Table V

Vehicle ID	Latitude	Longitude	Heading	Speed
9877	003268936	-11711635	North	35
8766	003254417	-11703531	South	40

4  
 5 As shown in Table V, the data from the probe vehicles 146 provides a probe  
 6 vehicle identification number uniquely identifying the probe vehicle 146. Additionally,  
 7 the data includes a latitude and longitude indicating the current position of the probe  
 8 vehicle 146, such as from a GPS system. The data also includes a heading and a current  
 9 speed. To provide an indication of traffic conditions on the road network 12, the central  
 10 facility 26 groups and statistically analyzes the data from numerous probe vehicles.

11 The central facility 26 may also receive traffic and road condition data from  
 12 historical data 148. Historical data 148 provides travel speeds for locations along the  
 13 road network 12 at various time intervals based on past traffic patterns. Historical data  
 14 148 may be based on analysis of traffic data collected over time from the commercial  
 15 traffic supplier 140, the road authority 142, the sensors 144, the probe vehicles 146 or any  
 16 other source. The analysis of the traffic data collected over time may illustrate repeating  
 17 patterns of travel speeds at certain times of the day and days of the week for certain road  
 18 segments. For example, on weekdays between 7 A.M. and 9 A.M., a certain highway  
 19 experiences moderate congestion. Furthermore, the commercial traffic supplier 72 may  
 20 provide a model of likely traffic conditions at various times, such as traffic conditions  
 21 near a sporting area after a sporting event.

22 In one embodiment, the central facility 26 receives traffic data from the historical  
 23 data 148 in a format illustrated in Table VI or other formats.

Table VI

Code	Direction	12:00	12:15	12:30	12:45	1:00	1:15	1:30	1:45
7234	Positive	50	55	55	50	55	50	50	50
7234	Negative	35	40	40	50	50	40	35	40
8345	Positive	40	35	30	30	35	40	50	55
8345	Negative	50	50	35	35	40	50	50	35

As shown in Table VI, the data provides a location reference code identifying traffic locations. Location reference codes ("Code") refer to specific locations that are spaced apart from each other along a road. In one embodiment, the location reference codes may correspond to point location identification codes used in the traffic location table 112. For example, the location reference code includes a country code, a location table identification number and a point location identification code. In an alternative embodiment, the location reference codes do not correspond to the location codes used in the traffic location table 112.

As shown in Table VI, the data indicating traffic speeds also provides a direction of traffic flow as either "Positive" or "Negative." The "Positive" direction refers to a predetermined direction along a road specified by a positive offset and specified by the next traffic location code on the road. The "Negative" direction refers to a predetermined direction along a road specified by a negative offset and specified by the previous traffic location code on the road.

The data also includes traffic speeds for the location on the road network 12 identified by the location reference code. The historical data 148 provides traffic speeds in fifteen-minute increments of time for each of the listed location reference codes or in another increments of time. The speed data indicates the traffic speeds for the past half hour, the current traffic speeds and predicted traffic speeds. For the illustration of Table VI, the time at which the historical data 148 was supplied to the central facility 26 was approximately 12:30.

The central facility 26 may also receive traffic and road condition data from other sources 150. Other sources include police reports, accident reports, commercial media traffic reports, helicopter observations, individuals and any other source. The data from

1 these other sources 150 may take a variety of formats including a format similar to that  
2 described above in conjunction with the road authority 142, text descriptions, or any  
3 other format. Additionally, an operator at the central facility 26 may manually enter and  
4 edit the traffic and road condition data with the user interface 76.

5 The central facility 26 receives the traffic and road condition data from the variety  
6 of sources through a variety of communication links including wireless communication  
7 links, direct communication links, and the Internet. The central facility 26 receives the  
8 traffic and road condition data from the variety of sources at various time intervals. For  
9 example, the central facility 26 may automatically receive data every five minutes or any  
10 other interval from the different sources. Additionally, the central facility 26 may request  
11 traffic and road condition data from the sources when needed. In one embodiment, the  
12 central facility 26 time and date stamps all received data records from each of the  
13 sources.

14 The traffic and road condition data received by the central facility 26 may have a  
15 variety of different formats. In one embodiment, the commercial traffic supplier 140  
16 provides a complete replacement set of traffic data every established time interval. In  
17 another embodiment, the commercial traffic supplier 140 provides an incremental update  
18 of traffic data indicating additions, deletions and changes to previously supplied traffic  
19 data. Furthermore, the commercial traffic supplier 140 may provide data indicating a  
20 current status of traffic flow and/or a forecast of future traffic conditions. The above data  
21 formats for the collected traffic and road condition data illustrate some of the possible  
22 data formats. In alternative embodiments, the collected traffic and road condition data  
23 may have a variety of different formats than illustrated above.

#### 24 25 D. Data Conversion

26 Because the central facility 26 may collect traffic and road condition data  
27 from a variety of sources, the traffic and road condition data including the location  
28 description, event description and/or duration description of the traffic or road condition  
29 may be in a variety of forms. Thus, at step 90 of Figure 4, the central facility 26 converts  
30 the collected data of the location description, event description and/or duration  
31 description into a unified format with the conversion subprogram 92. Figure 6 illustrates

1 the steps performed by the central facility 26 to convert the collected data into a set of  
2 traffic flow data and a set of traffic incident data.

3 Referring to Figure 6, at step 152, the central facility 26 geo-codes the location  
4 description of the collected data and rejects any data that cannot be geo-coded. The  
5 central facility 26 places the data that cannot be geo-coded in a rejected repository 154.  
6 To geo-code the collected data, the central facility 26 identifies the location on the road  
7 network 12 indicated by the location description of collected data. In one embodiment,  
8 the central facility 26 converts the location description into the point location  
9 identification code(s) 116 of the traffic location table 110 that corresponds with the  
10 location indicated by the location description of the collected data. Additionally, the  
11 central facility 26 identifies a direction corresponding with the location description as  
12 either positive or negative.

13 For the traffic and road condition data sources that provide the location  
14 descriptions using location reference codes and directions that correspond with the  
15 location identification codes and directions of the traffic location table 110, the central  
16 facility 26 does not have to geo-code the data. Rather, the central facility 26 verifies that  
17 each location reference code matches with a point location identification code in the  
18 traffic location table 12. Additionally, the central facility 26 verifies that the direction  
19 identified in the collected data matches with a direction in the traffic location table 12  
20 corresponding to the identified point location identification code. If the location  
21 reference code and direction of the collected data match with one of the point location  
22 identification codes and directions of the traffic location table 110, the central facility 26  
23 passes the data to step 158. If the location reference code and direction of the collected  
24 data do not match with one of the point location identification codes and directions of the  
25 traffic location table 110, the central facility 26 stores the data in the rejected repository  
26 154.

27 For the traffic and road condition data sources that that provide the location  
28 descriptions using location reference codes and directions that do not correspond with the  
29 location identification codes and directions used in the traffic location table 110, the  
30 central facility 26 geo-codes the data with a conversion table 156 (or other suitable data  
31 structure). The conversion table 156 converts the location reference codes and directions

1 assigned by the data supplier, such as the commercial traffic supplier 140, into point  
2 location identification codes and directions of the traffic location table 110. A method  
3 for forming the conversion table is disclosed in U.S. Patent Application No. 10/123,587,  
4 entitled "METHOD AND SYSTEM FOR USING REAL-TIME TRAFFIC  
5 BROADCASTS WITH NAVIGATION SYSTEMS", the entire disclosure of which is  
6 incorporated by reference herein. U.S. Patent Application No. 10/123,587 discloses a  
7 method and system in which a data structure is formed that relates a set of location  
8 reference codes assigned to locations along roads by a first data supplier to another set of  
9 location reference codes assigned to locations along roads by a second data supplier. If  
10 the conversion table 156 provides a match between the location reference code and  
11 direction of the collected data with one of the point location identification codes and  
12 directions of the traffic location table 110, the central facility 26 assigns the matched  
13 point location identification code and direction to the data and passes the data to step 158.  
14 If the conversion table does not provide a match between the location reference code and  
15 direction of the collected data match with point location identification code and direction  
16 of the traffic location table 110, the central facility 26 stores the data in the rejected  
17 repository 154.

18         The traffic and road condition data sources may provide location descriptions  
19 using descriptive information, such as a text description, a name, number, an  
20 alphanumeric description or other descriptions. For example, the location description  
21 may provide an address, a landmark, point of interest or any other information indicating  
22 a position on the road network. Additionally, the location description may provide a  
23 main road on which the traffic condition exists and a crossroad, landmark, point of  
24 interest or any other information proximate the traffic condition on the main road.  
25 Additionally, the location description may provide a main road on which the traffic  
26 condition exists, a start description indicating the beginning the of traffic condition on the  
27 main road and an end description indicating the end of the traffic condition. The start  
28 description may provide a crossroad, address, landmark, point of interest or any other  
29 information proximate the beginning of the traffic condition on the main road, and the  
30 end description may provide a crossroad, address, landmark, point of interest or any other

1 information proximate the end of the traffic condition on the main road or a distance from  
2 the beginning of the traffic condition.

3 In one embodiment, the central facility 26 geo-codes the location description of  
4 the collected data by matching the descriptive information to the point location  
5 identification codes and directions in the traffic location table 12. For the example of  
6 data provided by the road authority 142 illustrated in the first row of Table III, the central  
7 facility 26 identifies the main road name from the collected data ("I-5") and determines  
8 whether the main road name matches a road number 120 or road name 122 associated  
9 with one of the linear location identification codes in the traffic location table 110. For  
10 the example of "I-5," the central facility 26 determines that the corresponding linear  
11 location identification code is "00111." Next, the central facility 26 identifies the start  
12 cross road name from the collected data ("Camino De La Plaza") and determines whether  
13 the start cross road name matches a first name 124 of one of the point location  
14 identification codes associated with the identified linear location code. For the example  
15 of "Camino De La Plaza," point location identification code "04966" on linear location  
16 identification code "0111" has the first name 124 of "Camino De La Plaza." Next, the  
17 central facility 26 identifies the end cross road name from the collected data ("I-805")  
18 and determines whether the end cross road name matches a first name 124 of one of the  
19 point location identification codes associated with the identified linear location code. For  
20 the example of "I-805," point location identification code "04967" on linear location  
21 identification code "0111" has the first name 124 of "I-805." Thus, the central facility 26  
22 identified the point location identification codes corresponding to the location description  
23 of the collected data.

24 The central facility 26 may also determine the direction from the descriptive  
25 information by determining whether the point location identification code associated with  
26 the end cross road name is negatively offset 132 or positively offset 134 from point  
27 location identification code associated with the start cross road name. For this example,  
28 the direction is positive. The central facility 26 may also determine the direction by  
29 comparing the direction data "South Bound" from the road authority 142 to the first name  
30 124 and second name 126 associated with the identified linear location identification  
31 code. If the road names and direction of the collected data match with one of the point

1 location identification codes and directions of the traffic location table 110 as described  
2 above, the central facility 26 assigns the matched point location identification codes and  
3 direction to the data and passes the data to step 158. If the road names of the collected  
4 data do not match with one of the point location identification codes and directions of the  
5 traffic location table 110, the central facility 26 stores the data in the rejected repository  
6 154.

7 In one embodiment, the central facility 26 converts the descriptive information of  
8 the location description of the collected data into a point location identification code of  
9 the start of the traffic incident and an extent of a number of contiguous point location  
10 identification codes affected in a direction from the start of the traffic incident. In  
11 another embodiment, the central facility 26 converts the descriptive information of the  
12 location description of the collected data into a point location identification code of the  
13 start of the traffic incident and a point location identification code of the end of the traffic  
14 incident.

15 In an alternative embodiment, the central facility 26 geo-codes the location  
16 description in terms of descriptive information using the geographic database 84. The  
17 central facility identifies road segments and/or nodes of the geographic database 84 that  
18 match the descriptive information. For example, the location description that provides  
19 the address, landmark, point of interest or any other information indicating a position on  
20 the road network may be geo-coded with the geographic database 84 to identify the  
21 position on the road network. Once the location description has been geo-coded with the  
22 geographic database 84, the central facility 26 converts identified position on the road  
23 network to the point location identification codes and directions in the traffic location  
24 table 12.

25 For the traffic and road condition data sources that provide the location  
26 descriptions using latitude, longitude and heading, such as the plurality of probe vehicles  
27 146, the central facility 26 geo-codes the location description of the collected data by  
28 matching the latitude, longitude and heading to one of the point location identification  
29 codes and directions in the traffic location table 110. For the example of data provided  
30 by the probe vehicles 146 illustrated in the first row of Table V, the central facility 26  
31 identifies the point location identification code having latitude 136 and longitude 138

1 matching or close to the latitude and longitude of the collected data. For this example  
2 with collected data having latitude "03268936" and longitude "-11711635" matches with  
3 point location identification code 00529. The central facility 26 then identifies the  
4 direction by comparing the heading to the first name 124 or second name 126 associated  
5 with the linear location identification code of which the point location identification code  
6 belong. For the present example, the heading "North" corresponds to "Positive"  
7 direction.

8 Alternatively, the central facility 26 geo-codes the latitude, longitude and heading  
9 into one of the point location identification codes and directions in the traffic location  
10 table 110 by performing a map matching algorithm that identifies a main road  
11 corresponding to the latitude and longitude data. After determining the main road  
12 corresponding to the latitude and longitude data, the central facility 26 performs a cross  
13 road search algorithm that identifies a cross road near the latitude and longitude position.  
14 The map matching algorithm and cross road search algorithm use the geographic  
15 database 84 and may be any map matching algorithm and cross road search algorithm  
16 known to one skilled in the art. Once the main road and cross road are identified, the  
17 central facility identifies the point location identification code and direction in the manner  
18 described above with respect to the collected data supplied by the road authority 142. If  
19 the latitude, longitude and heading of the collected data match with one of the point  
20 location identification codes and directions of the traffic location table 110 as described  
21 above, the central facility 26 assigns the matched point location identification code and  
22 direction to the data and passes the data to step 158. If the latitude, longitude and  
23 heading of the collected data do not match with one of the point location identification  
24 codes and directions of the traffic location table 110, the central facility 26 stores the data  
25 in the rejected repository 154.

26 In an alternative embodiment, the central facility 26 geo-codes the location  
27 description in terms of latitude, longitude and heading using the geographic database 84.  
28 The central facility identifies road segments and/or nodes of the geographic database 84  
29 that match the latitude, longitude and heading. Once the location description has been  
30 geo-coded with the geographic database 84, the central facility 26 converts identified

1 road segments and/or nodes of the geographic database 84 to the point location  
2 identification codes and directions in the traffic location table 12.

3 In one embodiment, an operator at the central facility 26 may review the collected  
4 data placed in the rejected repository 154 to manually geo-code the data and pass the data  
5 to step 158.

6 After the collected data has been geo-coded, the central facility 26 determines the  
7 duration or end time from the duration description of the collected data and rejects any  
8 data that has expired at step 158. The central facility 26 converts the duration description  
9 of the collected data into a duration code or end time at which the traffic is expected to  
10 return to normal conditions. In one embodiment, the central facility 26 converts the  
11 duration description into the duration code or end time using a conversion table or other  
12 appropriate data structure or mathematical conversion. Once the central facility 26 has  
13 converted the duration description into the duration code or end time, the central facility  
14 determines whether the collected data has a duration code or end time that has expired.  
15 The central facility 26 places the data that has expired in an expired repository 160. If the  
16 data has not expired, the central facility 26 passes the data to step 162.

17 In another embodiment, the central facility 26 identifies data records whose time  
18 stamp as been exceeded by a predetermined amount of time and removes the data to the  
19 expired repository 158. The value of the predetermined amount of time may vary  
20 depending on the source of the collected data. For example, data from the sensors 144  
21 and probe vehicles 146 will expire sooner than collected data from the road authority  
22 144.

23 In one embodiment, the operator may review the expired data placed in the  
24 expired repository 160 to determine whether any of the data should not be classified as  
25 expired and may pass the data records to step 162.

26 At step 162, the central facility 26 determines an event type from the event  
27 description of the collected data. For the collected data that provide speed information,  
28 such as collected data from the sensors 144, probe vehicles 146, historical data 148 and  
29 commercial traffic supplier 140, the central facility 26 determines that the event type is  
30 congestion information that will eventually be stored in a traffic flow data repository 168.  
31 For the collected data providing traffic incident information, such as the road authority

1 142 and commercial traffic supplier 140, the central facility 26 converts the event code,  
2 event type or event descriptive information of the collected data into a traffic event code.  
3 In one embodiment, the central facility 26 converts the event description into the traffic  
4 event code using a conversion table or other appropriate data structure. In one  
5 embodiment, the traffic event codes are three-digit numbers associated with specific  
6 traffic incidents and road conditions including accidents, delays, traffic backups,  
7 construction activities, lane restrictions, traffic restrictions, exit restrictions, carriageway  
8 restrictions, road works, obstruction hazards, road conditions, dangerous vehicle and  
9 traffic equipment status or any other information regarding the road network 12. The  
10 traffic event codes may correspond exactly with the event codes established by the  
11 ALERT-C protocol.

12 For the traffic and road condition data sources that use event codes, such as the  
13 commercial traffic supplier 140, the central facility determines the traffic event code by  
14 matching the supplied event code to a traffic event code. If the commercial traffic  
15 supplier 140 uses identical event codes as traffic event codes, the central facility 26  
16 verifies that the event code matches with a traffic event code. If the commercial traffic  
17 supplier 140 uses event codes different from the traffic event codes, the central facility 26  
18 uses the conversion table to convert the supplied event code into a traffic event code. For  
19 the collected data from the road authority, the central facility 26 uses the conversion table  
20 matching the textual descriptions of the event type to the proper traffic event code.

21 If the event code, event type or event descriptive information of the collected data  
22 match with a traffic event code, the central facility 26 assigns the matched traffic event  
23 code to the data and passes the data to step 166. If the event code, event type or event  
24 descriptive information of the collected data do not match with the traffic event codes,  
25 the central facility 26 stores the data in the unresolved repository 164.

26 In one embodiment, the operator may review the data records placed in the  
27 unresolved repository 164 to determine the appropriate traffic event code and may pass  
28 the data records to step 164.

29 At step 164, the central facility 26 resolves any conflicting and/or duplicate data  
30 for identical locations along the road network 12. Because the central facility 26 receives  
31 traffic and road condition data from a variety of sources, several data records may

1 provide traffic information for the identical location as indicated by the point location  
 2 identification codes. In one embodiment, the central facility identifies data having  
 3 identical point location identification codes.

4 If the data having identical point location identification codes provide speed  
 5 information, the central facility 26 compares the speed information to determine if the  
 6 information is similar or conflicting. If the difference between current speed values from  
 7 different data for the same point location identification code is within a predetermined  
 8 amount, the central facility 26 identifies the data as duplicates. For duplicate data  
 9 records, the central facility 26 stores the data record with the most current (time-base)  
 10 data in the resolved traffic flow data repository 168 and stores the data with the less  
 11 current data in the unresolved repository 164. If the difference between traffic speed  
 12 values is not within the predetermined amount, the central facility 26 identifies the data  
 13 as conflicting. For conflicting data, the central facility 26 analyzes the data to determine  
 14 which data most likely represents the actual traffic speed of the identified location. In  
 15 one embodiment, the central facility 26 chooses the data record of the data sources that  
 16 ranks highest on a quality list developed by the central facility 26. The quality list may  
 17 be developed based on studies of the various data sources to determine which source  
 18 provides the most accurate traffic. For example, the quality list may rank the commercial  
 19 traffic provider 140 first, road authority 142 second, sensors 144 third, probe vehicles 146  
 20 fourth, historical data 148 fifth and other sources 150 last. The central facility 26 stores  
 21 the data from the highest ranked source in the resolved traffic flow data repository 168  
 22 and stores the other conflicting data in the unresolved repository 164. In another  
 23 embodiment, the central facility 26 chooses the data based on a consideration of both the  
 24 quality rank and the time age associated with the data. In yet another embodiment, the  
 25 operator may review the conflicting and/or duplicate data and investigate which data  
 26 record should be stored in the resolved traffic flow data repository 168.

27 After the central facility 26 has converted the collected data follow the steps of  
 28 Figure 6, the traffic incident data stored in the resolved traffic incident data repository  
 29 170 have a unified format. Each data record representing a traffic incident includes  
 30 components of event type code, start location code, direction, extent and end time or  
 31 duration as shown below:

Event Code	Location Code	Direction	Extent	End Time – Duration	
401	04967	Positive	1	4:30	2 hours

1  
2 Similarly, the traffic flow data stored in the resolved traffic flow data repository 168 have  
3 a unified format. Each data record representing traffic flow includes components of  
4 location code, direction, speed(s) and end time or duration. For example, the example  
5 illustrated below with Table VIII shows data records representing traffic flow.

6 The above description for resolving the collected data illustrates some of the  
7 possible methods for geo-coding, determining duration and event codes, resolving  
8 conflicting and duplicate data into a unified format. In alternative embodiments, other  
9 methods for geo-coding, determining duration and event codes, resolving conflicting and  
10 duplicate data into a unified format may be used. Additionally, the unified format for the  
11 traffic incident data and unified format for the traffic flow data may have a variety of  
12 different formats than illustrated above.

13

#### 14 E. Data Aggregation

15 The resolved traffic flow data repository 166 contains data representing the traffic  
16 speed at numerous identified locations along the same road or connected road segments  
17 14 of the road network 12 of the geographic region 10. At step 94 of Figure 4, the central  
18 facility 26 aggregates data representing contiguous locations have related speed  
19 conditions with the aggregation subprogram 96. Figure 7 illustrates the steps performed  
20 by the central facility 26 to aggregate data having related speeds.

21 Referring to Figure 7, the central facility 26 identifies locations with below  
22 normal speed at step 172. The central facility 26 evaluates the data stored in the resolved  
23 traffic flow repository 168 to identify the locations along the road network 12 having a  
24 current speed below a predetermined normal traffic flow speed. In one embodiment, the  
25 central facility 26 compares the current speed value associated with each identified  
26 location to a return to normal speed value associated with the identified location. If the  
27 current speed is less than the return to normal speed value, the central facility 26  
28 identifies the location as having a current speed below the predetermined normal traffic  
29 flow speed. Each linear location, and thus each point location, of the traffic location table

1 110 is assigned a speed category. Each speed category has a return to normal speed  
 2 value. Table VII illustrates an example of speed categories and their respective return to  
 3 normal speed values.

4  
 5 Table VII

Speed Category	Range in MPH	Return To Normal Value
1	>80	70
2	65-80	60
3	44-64	55
4	41-54	50
5	31-40	35
6	21-30	25
7	6-20	10
8	<6	5

6  
 7 As shown in Table VII, each speed category has a normal range of speeds and an  
 8 assigned return to normal speed value. For a road (linear locations and point locations of  
 9 the traffic location table 110 on that road) having a speed category 4, the normal range of  
 10 speeds is between 41 and 54 miles per hour and the return to normal speed value is 50  
 11 mile per hour. In one embodiment, the central facility 26 may override the speed  
 12 category and return to normal speed value assigned to a point location. For example, if  
 13 the point location corresponds with a curve on a speed category 2 linear location, the  
 14 central facility 26 may override the return to normal speed value of 60 to a speed value  
 15 more representative of expected speeds at the curve, such as 45 mile per hour.  
 16 Additionally, the central facility 26 may assign a specific return to normal speed value to  
 17 specific point locations. For example, if the point location corresponds with a tollbooth  
 18 on a speed category 2 linear location, the central facility 26 may assign the return to  
 19 normal speed value of more representative of expected speeds at the tollbooth, such as 15  
 20 mile per hour.

21 Table VIII illustrates data from the resolved traffic flow repository 168. For the  
 22 example in Table VIII, the current time is 2:30, the speed category of the identified

1 locations indicated by point location identification codes is 4 and the return to normal  
 2 speed value is 50 mile per hour. The central facility 26 evaluates the speed data for the  
 3 identified locations and identifies the locations having a current speed below the return to  
 4 normal speed value of 50 mile per hour. Additionally, the central facility identifies  
 5 whether the current traffic flow speed for the identified location will remain below the  
 6 return to normal speed value for future time intervals. For the data shown in Table VIII,  
 7 the central facility 26 will identify the bold items in the data as being below the return to  
 8 normal speed value of 50.

9 Table VIII

Code	Direction	2:00	2:15	2:30	2:45	3:00	3:15	3:30	3:45
01234	Positive	50	55	55	50	55	50	50	50
01234	Negative	35	40	<b>40</b>	50	50	40	35	40
02345	Positive	40	35	<b>30</b>	<b>30</b>	<b>35</b>	<b>40</b>	50	55
02345	Negative	50	50	<b>35</b>	<b>35</b>	<b>40</b>	50	50	35
03456	Positive	55	55	55	50	35	40	50	55
03456	Negative	50	50	<b>35</b>	<b>35</b>	50	50	50	35

10

11 After identifying the data having current traffic flow speeds below the return to  
 12 normal speed value, the central facility 26 creates below normal flow data records from  
 13 the identified data at step 174. The below normal flow data record includes components  
 14 of point location identification code, direction, current speed and end time for the traffic  
 15 flow speed to return to normal. Table IX illustrates the below normal traffic flow data  
 16 records created by the central facility from the data records of Table VIII. The below  
 17 normal traffic flow data records contain components identifying the traffic location  
 18 reference code, direction, current speed and end time for the traffic flow speed to return  
 19 to normal.

Table IX

Code	Direction	Current Speed	End Time
01234	Negative	40	2:45
02345	Positive	30	3:30
02345	Negative	35	3:15
03456	Negative	35	3:00

Referring to Figure 7, the central facility 26 aggregates adjacent point locations having below normal speeds into a single traffic congestion event at step 176. In one embodiment, the central facility 26 evaluates each point location along a linear location of the traffic location table 110 and aggregates adjacent point locations along the linear location that have current speeds within a predetermined range into a single congestion event. As described above, each linear location of the traffic location table 110 is a predefined portion of the road network 12 and may comprise several connected road segments 14. For example, the linear location may be an important road or highway, such as Lake Shore Drive or I-5.

To aggregate the point locations of the linear location having current speeds within a predetermined range, the central facility 26 evaluates the linear location from end to end, first in the positive direction and then in the negative direction. Point locations will be aggregated into a single event if the point locations are contiguous on the same linear location. Additionally, the central facility 26 will aggregate one point location with another contiguous point location if the speed associated with the point location is within a threshold value, such as 5, of the average of the speeds of aggregated point locations. In one embodiment, the central facility 26 will not aggregate point locations if the point location has a current speed that is more than the threshold value from the average of the aggregated point locations. In one embodiment, the central facility 26 will aggregate contiguous point locations even if the point locations belong to different linear locations. In an alternative embodiment, the central facility 26 will not aggregate point locations if the point locations belong to different linear locations. In another embodiment, the central facility 26 will aggregate contiguous point locations that have current speeds that fall within the same level of congestion range of traffic speeds.

Figure 8 illustrates a traffic linear 182 comprising point location identification codes 04450 through 04459. The current speed for the locations in the positive direction and negative direction are also provided in the Figure 8. For location 04451, the speed in the positive direction is 35 and the speed in the negative direction is 40. The below normal traffic flow data records for the traffic linear 182 are listed in Table X.

**Table X:**

Code	Direction	Current Speed	End Time
04450	Positive	40	2:45
04453	Positive	35	3:15
04453	Negative	30	3:00
04454	Positive	30	3:15
04454	Negative	25	3:00
04455	Positive	30	2:45
04455	Negative	25	3:30
04456	Positive	35	3:15
04456	Negative	35	3:00
04457	Positive	40	2:45
04457	Negative	40	3:30
04458	Positive	35	3:15
04458	Negative	40	3:00
04459	Positive	40	2:45
04459	Negative	40	3:30

For the example shown in Figure 8 and Table X, the central facility 26 begins the aggregation process for the positive direction of the traffic linear 182 with point location 04459. The central facility 26 compares the speed for the positive direction of point location 04459 to the speed for the positive direction of point location 04458 to determine if the speeds are with a threshold value, such as 5. The speed for the positive direction of point location 04458 is 40, the speed for the positive direction for point location 04458 is 35, thus the two point locations have related speeds, and the central facility 26 aggregates

1 the two point locations. Next, the central facility 26 compares the average of the  
2 associated speeds for the positive direction for point locations 04459 and 04458 of 37.5  
3 to the speed 40 for the positive direction associated with the next contiguous point  
4 location 04457. Since the speed for location code 04457 is within the threshold value of  
5 5 from the average of 37.5, the central facility 26 adds point location 04457 to the  
6 aggregation. Next, the central facility 26 compares the average of the speeds for the  
7 positive direction from point locations 04459, 04458 and 04457 of 38.3 to the speed 35 of  
8 point location 04456 for the positive direction. Since the difference between the average  
9 and the speed of point location 04456 is within the threshold value, the central facility 26  
10 adds point location 04456 to the aggregation of 04459, 04458 and 04457. Next, the  
11 central facility 26 compares the average of the speeds for the positive direction from  
12 locations 04459, 04458, 04457 and 04456 of 37.5 to the speed 30 of point location 04455  
13 for the positive direction. Since the difference between the average and the speed of  
14 point location 04455 is not within the threshold value, the central facility 26 does not add  
15 point location 04455 to the aggregation of 04459, 04458, 04457 and 04456. Thus, the  
16 central facility 26 aggregates point locations 04459, 04458, 04457 and 04456 in the  
17 positive direction together with an average speed of 37.5.

18 Continuing along the linear location 182 for the positive direction, the central  
19 facility 26 compares the speed of point location 04455 for the positive direction to the  
20 speed of point location 04454 for the positive direction to determine if the speeds are  
21 with the threshold value. The speed for the positive direction of point location 04455 is  
22 30 and the speed for point location 04454 for the positive direction is also 30, thus the  
23 two point locations have related speeds, and the central facility 26 aggregates the two  
24 point locations. Next, the central facility 26 compares the average of the associated  
25 speeds for point locations 04455 and 04454 for the positive direction of 30 to the speed  
26 for the positive direction associated with the next contiguous point location 04453. Since  
27 the difference between the speeds for point location 04453 of 35 is within the threshold  
28 value from the average of 30, the central facility 26 adds point location 04453 to the  
29 aggregation. Next, the central facility 26 determines that the next contiguous point  
30 location 04452 for the positive direction does not have below normal speed, so the point  
31 location 04452 is not aggregated with point locations 04455, 04454 and 04453. Thus, the

1 central facility 26 aggregates point locations 04455, 04454 and 04453 in the positive  
2 direction together with an average speed of 31.7. Because point locations 04452 and  
3 04451 for the positive direction do not have below normal traffic speeds, the central  
4 facility 26 moves to point location 04450 on the linear location 182. Because point  
5 location 04450 is the last point location on linear location 182, the central facility 26 does  
6 not aggregate point location 04450 with another point location in the positive direction,  
7 and the central facility 26 has complete evaluation of the positive direction of linear  
8 location 182. In an alternative embodiment, the central facility continues the above  
9 aggregation process to evaluate whether to aggregate point location 04450 with the next  
10 contiguous point location on the next traffic linear.

11 Next, the central facility evaluates the current speeds for the linear location 182  
12 for the negative direction starting with point location 04450 and steps through the point  
13 locations until reaching the opposite end point location 04459 of the linear location 182.  
14 For the negative direction, the central facility 26 aggregates point locations 04453, 04454  
15 and 04455 together with an average speed of 26.7, and the central facility 26 aggregates  
16 point locations 04456, 04457, 04458 and 04459 together with an average speed of 38.75.

17 After the central facility 26 has aggregated contiguous point locations with below  
18 normal speeds, the central facility 26 creates congestion event data records comprising  
19 the aggregated point locations and a representative speed of the aggregated point  
20 locations at step 178. In one embodiment, the representative speed of the aggregated  
21 point locations is the average speed of the aggregated point locations. In another  
22 embodiment, the representative speed is a weighted average speed of the aggregated  
23 point locations based on the road length between contiguous point locations. In another  
24 embodiment, the representative speed is a range of speeds of the aggregated point  
25 locations.

26 In one embodiment, the congestion event data records include components of start  
27 point location identification code, direction of traffic flow (positive or negative), extent of  
28 the congestion as represented by a number of contiguous point location identification  
29 codes affected in the direction of flow from the start point location identification code,  
30 event type code and end time after which the congestion event is no longer relevant. The

1 central facility 26 stores the congestion event data records in a congestion event  
2 repository 180.

3 To determine the event type code, the central facility 26 compares the average  
4 speed for the aggregated point locations to ranges of speed associated with event type  
5 codes. For example, Table XI illustrates event type codes with corresponding range of  
6 traffic flow speeds.

7 Table XI:

Range of Average Speed	Event Code
Average Speed < 9.0	70
9.0 < Average Speed < 15.0	71
15.0 < Average Speed < 22.0	72
22.0 < Average Speed < 28.0	73
28.0 < Average Speed < 35.0	74
35.0 < Average Speed < 43.0	75
43.0 < Average Speed	76

8  
9 For the congestion event data records, the central facility 26 determines the end  
10 time from the earliest end time associated with one of the point locations of the  
11 aggregation. In one embodiment, the end time is related to an ALERT-C duration code.  
12 Similar to the event type code, a range time corresponds to one of the duration codes.  
13 Table XII illustrates the time ranges and corresponding duration codes.  
14

1      Table XII:

Range of Times	Duration Code
Duration < 15 minutes	0
15 minutes < Duration < 30 minutes	1
30 minutes < Duration < 60 minutes	2
60 minutes < Duration < 120 minutes	3
120 < Duration < 180 minutes	4
180 minutes < Duration < 240 minutes	5
240 minutes < Duration < 480 minutes	6
Duration > 480 minutes	7

2  
3      For the example shown in Figure 8 and Table X, Table XIII illustrates the  
4 congestion event data records formed by the central facility 26 and stored in the  
5 congestion event repository 180. The aggregated traffic flow data represented by the  
6 congested event data records provide a model of the traffic flow conditions as would be  
7 perceived by a driver traveling the road representing by linear location 182. For example,  
8 the driver traveling in the positive direction would experience moderate congestion  
9 between locations represented by point location identification code 04456 and 04459 and  
10 would experience more serious congestion between locations represented by point  
11 location identification code 04453 and 04455.

12  
13      Table XIII:

Location Code	Direction	Extent	End Time/ Duration Code	Event Code
04450	Positive	0	2:45 / 0	75
04453	Positive	2	2:45 / 0	74
04456	Positive	3	2:45 / 0	75
04459	Negative	3	3:00 / 1	75
04455	Negative	2	3:00 / 1	73

14  
15      The above description for aggregating traffic flow data having below normal

1 speed conditions illustrates one embodiment. Alternative embodiments for aggregating  
2 traffic flow data having below normal speed conditions are possible.

3 According to one alternative embodiment, the central facility 26 aggregates all  
4 traffic flow data not just the locations having below normal traffic speed. By aggregating  
5 all traffic flow data, the central facility 26 not only identifies portions of the road network  
6 experiencing congestion but also portions of the road network experiencing normal traffic  
7 flow.

8 In another embodiment, the central facility 26 may perform statistical analysis to  
9 aggregate the locations and to reduce the affect of outlier speed values, such as no  
10 reported speeds or abnormal speeds. The central facility 26 may consider aggregating a  
11 location that has no reported speed or an abnormal speed with surrounding locations. For  
12 example, locations 01111, 01112 and 01113 each have a current speed of 25, location  
13 01114 located a quarter of a mile from location 01113 has no reported speed, location  
14 01115 located a quarter of a mile from location 01114 has a speed of 25, and locations  
15 01116 and 01117 have a current speed of 25. In this example, because location 01114 is  
16 a short distance between two stretches of locations having similar speeds, locations  
17 01111 through 01117 may be aggregated together even though location 01114 has no  
18 reported speed. In another embodiment, the central facility 26 considers the previously  
19 reported speed of a location that has no currently reported speed or an abnormal speed.  
20 For example, locations 01111, 01112 and 01113 each have a current speed of 25, location  
21 01114 has no currently reported speed but reported a speed of 25 five minutes prior,  
22 location 01115 and locations 01116 and 01117 have a current speed of 25. In this  
23 example, because location 01114 had a previously reported similar speed to the current  
24 speeds of the other locations, locations 01111 through 01117 may be aggregated together  
25 even though location 01114 has no reported speed.

26 In another alternative embodiment, in addition to aggregating locations having  
27 related speeds, the central facility 26 may consider the distance separating adjacent  
28 locations. For example, locations 01111, 01112 and 01113 each have a current speed of  
29 25, location 01114 located a quarter of a mile from location 01113 has a current speed of  
30 35, location 01115 located a quarter of a mile from location 01114 has a speed of 25, and  
31 locations 01116 and 01117 have a current speed of 25. In this example, because location

1 01114 is located a short distance between two stretches of locations having similar  
 2 speeds, locations 01111 through 01117 may be aggregated together even though the  
 3 speed at location 01114 is outside the threshold value.

4

#### 5 F. Data Prioritization

6 The congestion events repository 180 and the resolved traffic incident data  
 7 repository 170 contain numerous data records representing the traffic and road conditions  
 8 at numerous locations along the road network 12 of the geographic region 10. Due to the  
 9 large number of records, at step 96 of Figure 4, the central facility 26 prioritizes the data  
 10 records with the prioritization subprogram 100. Data prioritization may be important  
 11 because a limited number or subset of the messages may be broadcasted and/or processed  
 12 by the navigation system 30. For example, the number of traffic messages 22  
 13 broadcasted or handled by the navigation system 30 may be limited to a fixed number,  
 14 such as one hundred messages. Additionally, it is desirable to prioritize traffic messages  
 15 because the navigation system 30 may wish to process the messages with a higher  
 16 priority first. Moreover, the broadcaster may desire to broadcast the traffic messages  
 17 with a higher priority more frequently than the messages having a lower priority. Figure  
 18 7 illustrates the steps performed by the central facility 26 to prioritize the congestion  
 19 event and resolved incident data records into a set of prioritized traffic data records.

20 At step 184, the central facility 26 determines a length of the road network 12  
 21 affected by each congestion event and traffic incident. In one embodiment, the central  
 22 facility 26 uses a road length table 186 stored in memory that contains an actual road  
 23 length value between each adjacent location represented with the point location  
 24 identification codes. For example, for the congestion event that begins at point location  
 25 04450 and extends 3 point locations to location code 4453, the central facility 26 sums  
 26 the road length values from the road length table 186 between locations 4450 and 4451,  
 27 between locations 4451 and 4452, between locations 4452 and 4453 to determine the  
 28 length of the congestion event.

29 After determining the road length value affected by each of the congestion events  
 30 stored in the congestion event repository 180 and the traffic incident data repository 180,  
 31 the central facility 26 prioritizes the congestion events and traffic incidents based on their

1 associated road length values at step 188. In one embodiment, the central facility 26  
2 prioritizes the congestion event or traffic incident with the longest associated road length  
3 value as first, the next event or incident with the second longest associated road length  
4 value as second and so on in sequence until all of the congestion events or traffic  
5 incidents are prioritized. In another embodiment, the central facility 26 assigns priority  
6 levels to the events or incidents. For example, the events or incidents with the longest  
7 associated road length value are assigned the highest priority while events and incidents  
8 with smaller associated road length values are assigned lower priority.

9 At step 190, the central facility modifies the priority of the prioritized congestion  
10 events and traffic incidents based on event codes. In one embodiment, traffic incidents  
11 are given higher priority over congestion events. Additionally, certain incidents, such as  
12 lane closures, are given higher priority than other incidents, such as traffic equipment  
13 status. The central facility 26 may select traffic incidents having an associated high  
14 priority event code and modify their priority upward. That is, one traffic incident with a  
15 high priority event code is given a higher priority than traffic incidents and congestion  
16 events having longer associated road lengths. In one embodiment, the central facility 26  
17 modifies the priority of traffic incidents and congestion events within predetermined  
18 ranges of road lengths. For example, the central facility 26 may use event code to reorder  
19 the priority of all congestion events and traffic incidents that have associated road lengths  
20 within an established range of road lengths, such as from one to two miles of road length.

21 At step 192, the central facility 26 modifies the priority of the prioritized  
22 congestion events and traffic incidents based on road type. In one embodiment, the  
23 central facility 26 may select traffic incidents and congestion events on expressways and  
24 major arterial roads and modify their priority upward ahead of traffic incidents and  
25 congestion events on less important roads. That is, one traffic incident on an expressway  
26 is given a higher priority than traffic incidents and congestion events on less important  
27 road types. In one embodiment, the traffic location table 110 may identify which linear  
28 locations have the high priority by providing a rank or weighting factor. In one  
29 embodiment, the central facility 26 modifies the priority of traffic incidents and  
30 congestion events according to road type within predetermined ranges of road lengths.  
31 For example, the central facility 26 may use road type to reorder the priority of all

1 congestion events and traffic incidents that have associated road lengths within an  
2 established range of road lengths, such as from one to two miles of road length.

3 At step 194, the central facility 26 modifies the priority of the prioritized  
4 congestion events and traffic incidents based on point location identification code  
5 encompassed by the congestion events and traffic incidents. Similar to modifying  
6 priority by road type, the central facility 26 may select traffic incidents and congestion  
7 events that include important point locations and modify their priority upward ahead of  
8 traffic incidents and congestion events that include less important point locations. That  
9 is, one traffic incident that includes a point location representing a critical junction on an  
10 expressway is given a higher priority than traffic incidents and congestion events  
11 including less important point locations. In one embodiment, the traffic location table  
12 110 may identify which point locations have the high priority by providing a rank or  
13 weighting factor. In one embodiment, the central facility 26 modifies the priority of  
14 traffic incidents and congestion events within predetermined ranges of road lengths. For  
15 example, the central facility 26 may use point location identification codes to reorder the  
16 priority of all congestion events and traffic incidents that have associated road lengths  
17 within an established range of road lengths, such as from one to two miles of road length.

18 At step 196, the central facility 26 modifies the priority of the prioritized  
19 congestion events and traffic incidents based on co-location with or connection to another  
20 event or incident. In one embodiment, congestion events related to traffic incidents are  
21 given lower priority over congestion events for which there is no related traffic incident.  
22 The central facility 26 identifies congestion events that share point location identification  
23 codes with traffic incidents and modifies the priority of the congestion event downward.  
24 That is, the central facility 26 lowers the priority of a congestion event sharing a group of  
25 point location identification codes with a traffic incident, such as an accident. In one  
26 embodiment, the central facility 26 modifies the priority of traffic incidents and  
27 congestion events within predetermined ranges of road lengths. For example, the central  
28 facility 26 may use co-location or connection of the events or incidents to reorder the  
29 priority of all congestion events and traffic incidents that have associated road lengths  
30 within an established range of road lengths, such as from one to two miles of road length.

1           At step 198, the central facility 26 modifies the priority of the prioritized  
2 congestion events and traffic incidents based on direction associated with the congestion  
3 events and traffic incidents. At certain times of the day, such as during morning rush  
4 hour, the majority of the vehicles using the road network may be traveling in a direction  
5 toward the center of a city. Accordingly, the central facility 26 modifies the priority of  
6 the congestion events and traffic incidents to give higher priority to congestion events  
7 and traffic incidents having a direction component that corresponds to a preferred  
8 direction, such as into the city center during morning rush hour. The central facility 26  
9 may select traffic incidents and congestion events that include the preferred direction and  
10 modify their priority upward ahead of traffic incidents and congestion events that include  
11 less important direction. That is, one traffic incident that includes the preferred direction  
12 is given a higher priority than traffic incidents and congestion events including less  
13 important directions. In one embodiment, the central facility 26 modifies the priority of  
14 traffic incidents and congestion events within predetermined ranges of road lengths. For  
15 example, the central facility 26 may use direction to reorder the priority of all congestion  
16 events and traffic incidents that have associated road lengths within an established range  
17 of road lengths, such as from one to two miles of road length.

18           Furthermore, at step 200, the central facility 26 may modify the priority of the  
19 prioritized congestion events and traffic incidents based on duration or any other factor.

20           After the central facility 26 has prioritized the congestion events and traffic  
21 incidents, the central facility 26 stores the prioritized congestion events and traffic  
22 incidents in a prioritized traffic data repository 202.

23           Data prioritization is advantageous because a selected number of traffic messages  
24 for broadcast may be selected based on the established priority with the higher priority  
25 messages selected before the lower priority messages. Additionally, the traffic messages  
26 may be broadcast and/or processed by the navigation system 30 based on the established  
27 priority with the higher priority messages selected for broadcast and/or processing before  
28 the lower priority messages. Additionally, traffic messages with a higher priority may be  
29 broadcasted more frequently than messages with a lower priority.

30           The above description for prioritizing the congestion events and traffic incidents  
31 illustrates one embodiment. Alternative embodiments for prioritizing the congestion

1 events and traffic incidents are possible. Alternatively, rather than creating a priority  
 2 based on road length and modifying the priority based on road length, any other factor  
 3 may be used to create the original priority, such as event code, duration, road type or any  
 4 other factors. Additionally, each factor may be weighted to determine an appropriate  
 5 prioritization. For example, the priority may be based upon a score provided by a  
 6 weighted equation considering numerous factors, such as road length, event code,  
 7 duration, road type or any other factors.

8

## 9 G. Data Formatting

### 10 1. General Formatting

11 Referring to Figure 4, the central facility 26 formats the prioritized traffic data  
 12 stored in the prioritized traffic data repository 202 into traffic messages 22 with a  
 13 formatting subprogram 104. In one embodiment, the central facility 26 may provide the  
 14 traffic messages 22 in a variety of different formats for transmission by different  
 15 broadcasters and for use with different end users. Figure 10 illustrates one example of  
 16 the data components of a traffic message 22. The traffic message 22 includes the  
 17 following data components: an event description 22(1), a location 22(2), a direction  
 18 22(3), an extent 22(4), a duration 22(5) and advice 22(6). In alternative embodiments,  
 19 the traffic message 22 may also include components that provide other information 22(n).

20 The event description component 22(1) may include data that describe a traffic  
 21 event type 22(1)(1) along with data that describe a level of severity 22(1)(2) of the traffic  
 22 condition 22(1)(1). By convention, the location portion 22(2) of a message 22 specifies  
 23 the location at which a traffic queue begins. This location may be referred to as the  
 24 primary location or the head. The message 22 also indicates a secondary location or tail.  
 25 The message 22 indicates the secondary location indirectly, i.e., by means of the direction  
 26 and extent 22(4). The extent 22(4) indicates how many location codes from the primary  
 27 location are affected at the level of severity (i.e., 22(1)(2)) indicated in the message. The  
 28 direction component 22(3) includes data that indicate the direction of traffic affected.  
 29 The duration component 22(5) provides an expected amount of time that the traffic  
 30 condition will likely exist. The advice component 22(6) provides a recommendation for a  
 31 diversion of route.

1 According to one embodiment, the traffic message 22 conforms to the standard  
 2 format for ALERT-C messages established in the RDS-TMC system. For example, in  
 3 the RDS-TMC system, the event description 22(1), including description 22(1)(1) and  
 4 severity 22(1)(2), is an ALERT-C event code, and the duration 22(5) is an ALERT-C  
 5 duration code. In the RDS-TMC system, the location 22(2) portion of the message 22  
 6 includes a RDS-TMC location code 204. The RDS-TMC location code 204 includes a  
 7 location number 204(1), a location table number 204(2), a country code 204 (3), and a  
 8 direction 204(4). The location number 204(1) is a unique number within a region to  
 9 which one location table (i.e., a database of numbers) corresponds. The location table  
 10 number 204(2) is a unique number assigned to each separate location table. The country  
 11 code 204(3) is a number that identifies the country in which the location referenced by  
 12 the location number 204(1) is located. The direction 204(4) takes into account bi-  
 13 directionality.

14 The central facility 26 may format the prioritized traffic data into traffic messages  
 15 22 that correspond to the ALERT-C messages established in the RDS-TMC system.  
 16 Additionally, different traffic message formats are possible. The different traffic message  
 17 formats may have event descriptions, location descriptions or duration descriptions  
 18 different from the format of the ALERT-C messages. To format the prioritized traffic  
 19 data into traffic messages 22, the central facility 26 performs the steps illustrated in  
 20 Figure 11.

21 Referring to Figure 11, at step 206, the central facility 26 formats the event code  
 22 component of each data record of the prioritized traffic data to provide the event  
 23 description component 22(1) of the traffic messages 22. The event description  
 24 component 22(1) may be in the form of a textual description of the event and its severity,  
 25 an event code according to RDS-TMC ALERT-C protocol or any other appropriate form.  
 26 If necessary, the central facility 26 converts the event code associated with each record of  
 27 the prioritized traffic data into the desired event description format with a conversion  
 28 table (or other suitable data structure).

29 At step 208, the central facility 26 formats the point location identification code,  
 30 direction and extent components of each data record of the prioritized traffic data to  
 31 provide the location 22(2), direction 22(3) and extent 22(4) components of the traffic

1 messages 22. The location 22(2), direction components 22(3) may be in the form of  
2 location codes similar or different from the point location identification codes and  
3 directions of the traffic location table 110, a textual description of the location, direction  
4 and extent or any other appropriate form. If necessary, the central facility 26 converts the  
5 point identification location code, direction and extent associated each data record of the  
6 prioritized traffic data into the desired location code, direction and extent with a  
7 conversion table (or other suitable data structure) in a similar manner as discussed above  
8 in conjunction with resolving the collected data. The central facility 26 may convert the  
9 point identification location code, direction and extent associated each record of the  
10 prioritized traffic data into a textual description of the location using the road number  
11 120, road name 122 and first name 124 components of the point location identification  
12 code in the traffic location table 110. For example, the textual description may provide  
13 the main road, a cross road at which the traffic incident begins and cross road at which  
14 the traffic incident ends.

15 At step 210, the central facility 26 formats the duration component of each data  
16 record of the prioritized traffic data to provide the duration component 22(5) of the traffic  
17 messages 22. The duration component 22(5) may be in the form of an amount of time  
18 until the traffic condition is expected to end, a time and date at which the traffic condition  
19 is expected to end, a duration code according to RDS-TMC ALERT-C protocol or any  
20 other appropriate form. If necessary, the central facility 26 converts the duration  
21 associated each record of the prioritized traffic data into the desired duration form with a  
22 conversion table (or other suitable data structure).

23 At step 212, the central facility 26 identifies a possible alternative route to avoid  
24 the traffic condition for each data record of the prioritized traffic data for the advice  
25 component 22(6) of the traffic messages 22. To generate the advice component 22(6),  
26 the central facility 26 performs navigation functions using the prioritized traffic data. In  
27 one embodiment, central facility 26 includes methods and programming such as disclosed  
28 in U.S. Patent No. 6,438,561, entitled "METHOD AND SYSTEM FOR USING REAL-  
29 TIME TRAFFIC BROADCASTS WITH NAVIGATION SYSTEMS." U.S. Patent No.  
30 6,438,561 discloses a method and system in which location reference codes used in the

1 prioritized traffic data records are used to provide route calculation that considers traffic  
2 conditions.

3

## 4 2. Formatting for Geographic Location Filtering

5 Because the central facility 26 may develop traffic messages 22 for a large  
6 geographic region 10, such as the continental United States of America, the central  
7 facility 26 formats the prioritized traffic data, and thus the traffic messages 22, for  
8 geographic location filtering at step 214 of Figure 11. In one embodiment, the central  
9 facility 26 defines broadcast service areas 218 in the geographic region 10 as shown in  
10 Figure 12. Each broadcast service area 218 contains a portion of the road network 12.  
11 Each broadcast service area 218 may cover different portions of the road network 12 or  
12 same portions of the road network. For example, one broadcast service area 218 may  
13 cover the Los Angeles metropolitan area, another broadcast service area 218 may cover  
14 the San Diego metropolitan area, and still another broadcast service area 218 may cover  
15 both the Los Angeles metropolitan area and the San Diego metropolitan area.

16 In one embodiment, the traffic provider 24 predefines the broadcast service areas  
17 218 and identifies which roads and locations are included within each of the broadcast  
18 service areas 218. In another embodiment, the broadcaster predefines the broadcast  
19 service areas 218 and identifies which roads and locations are included within each of the  
20 broadcast service areas 218.

21 In one embodiment, the traffic location tables 110 include the broadcast service  
22 areas 218 as the area locations in the location type column 118 (see Figure 5). Each  
23 broadcast service area 218 has a location identification code, such as 00001 and 00002.  
24 The roads and locations along the roads (linear locations and point locations of the traffic  
25 location table 110) included in each of the broadcast service areas 218 contain the  
26 identification code of their respective broadcast service areas in the area reference  
27 column 128. In another embodiment, the central facility 26 establishes a broadcast  
28 service area data structure that identifies the roads and locations along the roads included  
29 in each of the broadcast service areas 218. In one embodiment, linear locations and point  
30 locations may be located in multiple broadcast service areas.

1           To allow geographic location filtering of the traffic messages 22, the central  
2 facility 26 associates each of the data records of the prioritized traffic data with the  
3 broadcast service area code 220 corresponding to the broadcast service area 218 in which  
4 the traffic condition is located. In one embodiment, the central facility 26 incorporates  
5 the broadcast service area code 220 into the location component 22(2) of the traffic  
6 message 22 (see Figure 10). For example, the broadcast service area code 220 may be  
7 incorporated into the message in a similar manner as the location table number 204(2)  
8 and the country code 204(3) in the RDS-TMC system.

9           Associating traffic messages 22 with the broadcast service area code 220 allows  
10 the navigation system 30 to perform geographic location filtering on the received traffic  
11 messages 22. The navigation system 30 that receives the traffic messages 22 may use the  
12 broadcast service area code 220 to filter the received traffic messages into a set that is  
13 more geographically relevant to the current location of the vehicle 16. For example, if  
14 the vehicle 16 is located in the Los Angeles metropolitan area, the navigation system 30  
15 may filter the received traffic messages to obtain a set of messages having the broadcast  
16 service area code 220 corresponding to the Los Angeles metropolitan area. Additionally,  
17 the traffic messages 22 may be filtered to obtain messages having the broadcast service  
18 area code(s) 220 as specified by the user of the navigation system 30 or the user of the  
19 non-vehicle 18. Furthermore, the navigation system 30 may filter the traffic messages to  
20 obtain messages having broadcast service area codes 220 corresponding to a planned  
21 route. Moreover, the navigation system 30 may filter the traffic messages to obtain  
22 messages having the broadcast service area codes 220 corresponding to the extent of a  
23 map display associated with the navigation system 30. In another embodiment, the traffic  
24 messages may be filtered to obtain messages having the broadcast service area codes 220  
25 corresponding to subscription information. For example, a driver may subscribe to a  
26 broadcasting service to receive traffic messages for the Los Angeles metropolitan area.

27           After filtering the received traffic messages, the navigation system 30 processes  
28 the traffic messages 22 in their prioritized order. By performing geographic location  
29 filtering using the broadcast service area code, the navigation system may process  
30 significantly less information to provide traffic related features.

1        Associating traffic messages 22 with the broadcast service area code 220 also  
2 allows the traffic provider 24 to perform geographic location filtering of the traffic  
3 messages 22 to transmit only a subset of the messages 22 to the broadcaster. The  
4 broadcaster may want traffic messages 22 describing traffic conditions in only specific  
5 geographic areas and not all of the geographic areas. The traffic provider may use the  
6 broadcast service area code 220 to filter the traffic messages 22 to a set that relate to  
7 conditions within the geographic areas specified by the broadcaster. Then, the traffic  
8 provider 24 transmits the desired set of traffic messages 22 to the broadcaster. For  
9 example, if the broadcaster only wants traffic messages 22 for the Los Angeles  
10 metropolitan area, the traffic provider 24 would filter the traffic messages to obtain a set  
11 of messages having the broadcast service area code 220 corresponding to the Los  
12 Angeles metropolitan area.

13        Associating traffic messages 22 with the broadcast service area code 220 also  
14 allows the broadcaster to perform geographic location filtering of the traffic messages 22.  
15 The broadcaster may have separate broadcast equipment for different geographic areas  
16 and wish to broadcast traffic messages 22 describing traffic conditions in each of the  
17 separate geographic areas with the separate broadcast equipment. The broadcaster may  
18 use the broadcast service area code 220 to filter the traffic messages 22 into different sets  
19 that relate to conditions within each of the geographic areas. Then, the broadcaster  
20 transmits the desired set of traffic messages 22 with the specified broadcast equipment.  
21 For example, if the broadcaster has broadcast equipment in the Los Angeles metropolitan  
22 area and the San Diego metropolitan area, the broadcaster would filter the traffic  
23 messages to obtain one set of messages having the broadcast service area code 220  
24 corresponding to the Los Angeles metropolitan area and another set having the broadcast  
25 service area code 220 corresponding to the San Diego metropolitan area.

26        The broadcast service area codes 220 provide significantly more precise  
27 geographic location filtering than provided in the RDS-TMC system. The country code  
28 204(3) and location table number 204(2) in the RDS-TMC system only identify the  
29 traffic table containing the location(s) specified by the message. The country code 204(3)  
30 identifies which set of traffic tables must be used, i.e., the traffic tables pertaining to the  
31 specified country of the country code.

1           Currently, the traffic table numbers are used for versioning, expansion or for  
2 distinction between location numbering authorities. Versioning refers to the retiring of  
3 old numbers, and expansion refers to a new table either replacing or supplementing an  
4 existing table. Current table numbers have been assigned to broad geographic regions  
5 including multiple states and multiple metropolitan areas. Once established, table  
6 numbers are difficult to reassign or reorganize. For example, all interested parties,  
7 including governmental agencies, must agree to the division and organization of  
8 geographies between tables. Additionally, once a table number has been assigned, the  
9 table number cannot be reassigned. Because the table numbers cannot be reassigned,  
10 geographic areas already established and organized by table numbers cannot be split,  
11 combined or modified in the future. Furthermore, expanding the table number to support  
12 more than the current 64 tables of the ALERT-C format would require physical structure  
13 change in many of the existing applications that use the traffic tables.

14           For these reasons, table numbers only enable broad geographic filtering. A single  
15 traffic location table may include locations that cover multiple metropolitan areas. A  
16 single country may also include multiple metropolitan areas. The broadcast service area  
17 codes 220 allow many applications to perform geographic location filtering at a more  
18 detailed level than provided in the RDS-TMC system, such a filtering by metropolitan  
19 area or other geographic areas, while supporting the established table numbers.

20

#### 21           H.     Traffic Message Distribution

22           Referring to Figure 4, the central facility 26 distributes the formatted traffic  
23 messages 22 for broadcast at step 106 with a distribution subprogram 108. In one  
24 embodiment, the central facility 26 may distribute the traffic messages 22 to a variety of  
25 different broadcasters. One commercial broadcaster may desire to receive all of the  
26 traffic messages 22 formed from the prioritized traffic data records while another  
27 commercial broadcaster may desire to receive a subset of the traffic messages 22 formed  
28 from the prioritized traffic data records. To accommodate the different broadcasters, the  
29 central facility 26 filters the traffic messages 22 into a desired set of traffic messages 22  
30 as specified by the broadcaster.

1           For example, if the central facility 26 has traffic messages 22 that describe traffic  
2 conditions across the United States, a broadcaster may desire only a set of the traffic  
3 messages 22 that relate to traffic conditions in the Los Angeles metropolitan area. For this  
4 example, the central facility 26 performs geographic area filtering on the traffic messages  
5 22 to obtain a set of traffic messages that have the broadcast service area code  
6 corresponding to the Los Angeles metropolitan area. The central facility 26 then  
7 distributes the set of traffic messages that have the broadcast service area code  
8 corresponding to the Los Angeles metropolitan area to the broadcaster. Additionally, the  
9 central facility 26 may perform geographic location filtering to provide a subset of the  
10 traffic messages 22 that occur on certain specified roads. For filtering by road, the  
11 central facility 26 filters the traffic messages 22 using the linear location identification  
12 code associated with the point location identification codes of the traffic messages 22.

13           The central facility 22 also filters the traffic messages 22 by a number of  
14 messages desired by the broadcaster. For example, the broadcaster may desire a set of  
15 two hundred traffic messages 22. The central facility 22 provides the first two hundred  
16 traffic messages 22 formed from the prioritized traffic data records. Additionally, the  
17 broadcaster may desire a set of twenty traffic messages for the Los Angeles metropolitan  
18 area. To provide the set of twenty Los Angeles traffic messages, the central facility 26  
19 performs geographic area filtering on the traffic messages 22 from the prioritized traffic  
20 data records to obtain a set of traffic messages that have the broadcast service area code  
21 corresponding to the Los Angeles metropolitan area. Next, the central facility provides the  
22 first twenty messages from the set of traffic messages relating to the Los Angeles  
23 metropolitan area.

24           In one embodiment, the central facility 26 transmits the traffic messages 22 to the  
25 broadcaster with a streaming data feed comprised of packets of messages. A packet is a  
26 group of traffic messages packaged in a manner to control the delivery and verification of  
27 data in controllable data sizes. Each traffic message 22 is contained entirely within one  
28 of a series of traffic packets. Figure 13a illustrates a traffic packet 222 including a first  
29 header 222(1), a second header 222(2), a service provider message 222(3) and one or  
30 more traffic messages 222(4).

1       The first and second headers 222(1) and 222(2) indicate the start of the service  
 2       provider message component 222(3) and the traffic message components 222(4).  
 3       Additionally, the headers verify data accuracy independent of the streaming transport  
 4       layer as known to those skilled in the art.

5       Figure 13b illustrates a format of the service provider message 222(3) of the  
 6       traffic packet 222. The service provider message 222(3) contains five bytes. The service  
 7       provider message 222(3) has the format of an ALERT-C message as specified by the  
 8       RDS-TMC system. The service provider message 222(3) reserves bits 7-5 of byte 1. Bit  
 9       4 of byte 1 specifies the message type that is set to 1 to indicate the service provider  
 10      message. Bits 3-0 of byte 1 identify the service and traffic location table provider. Bits  
 11      7-2 of byte 2 identifies the traffic location table number (table identification number 114  
 12      of Figure 5) containing the location information (point location identification code 116 of  
 13      Figure 5) provided in the following traffic message component 222(4). Bits 1-0 of byte 2  
 14      and bits 7-6 of byte 3 are reserved.

15      In the service provider message 222(3), bits 7-0 of bytes 4 and 5 identify the  
 16      broadcast service area code 220 of the location information provided in the following  
 17      traffic message(s) 222(4). Typically, bits 7-0 of bytes 4 and 5 of the ALERT-C message  
 18      as specified by the RDS-TMC system are used to identify alternative frequency  
 19      information. The alternative frequency information specifies the frequencies of other  
 20      broadcasts provided by a network radio stations that broadcast the same traffic service.  
 21      By identifying the broadcast service area code 220 using the portion of the ALERT-C  
 22      message normally reserved for alternative frequency information, the service provider  
 23      message identifies the broadcast service area code 220 for use by the end user or  
 24      broadcaster for geographic location filtering of the traffic messages. Using the portion  
 25      normally reserved for alternative frequency information provides advantage when  
 26      broadcast is by satellite radio or cellular phone in which the alternative frequency  
 27      information is non-applicable.

28      Figure 13c illustrates a format of the traffic message 222(4) of the traffic packet  
 29      222. Each traffic message 222(4) contains five bytes. The traffic message 222(4) shown  
 30      in Figure 13c has the format of an ALERT-C single group message as specified by the  
 31      RDS-TMC system. The traffic message 222(4) reserves bits 7-5 of byte 1. Bit 4 of byte

1 1 specifies the message type that is set to 0 to indicate the traffic message or ALERT-C  
 2 message. Bit 3 of byte 1 is set to zero identifying that the ALERT-C message is a single  
 3 group message type. The traffic message 222(4) may also have the format of multi-group  
 4 ALERT-C message as known to one skilled in the art.

5 Referring to Figure 13c, bits 2-0 of byte 1 provides the duration code 22(5)  
 6 indicating the expected duration of the traffic condition identified in the traffic message  
 7 222(4). Bit 7 of byte 2 provides a diversion 22(6) that is set to zero recommending no  
 8 diversion. Bit 6 of byte 2 provides the direction 22(3) of traffic flow affected by the  
 9 traffic condition (0 represents positive direction, 1 represents negative direction). Bits 5-  
 10 3 of byte 2 provide the extent 22(4) of the traffic condition. Bits 2-0 of byte 2 and bits 7-  
 11 0 of byte 3 provide the event code 22(1) of the traffic condition. Bits 7-0 of bytes 4 and 5  
 12 provide location information 22(2) (point location identification code 116 of Figure 5).

13 In one embodiment, more than one traffic message 222(4) follows the service  
 14 provider message 222(3). All traffic messages 222(4) following a service provider  
 15 message 222(3) are related to the traffic location table identification number and  
 16 broadcast service area code contained in the last service provider message 222(3). If the  
 17 traffic location table identification number or broadcast service area code changes for the  
 18 next traffic message 222(4), the service provider message 222(3) indicating the new  
 19 traffic location table identification number or broadcast service area code is supplied  
 20 before the next traffic message 222(4).

21 The above description for distributing the traffic messages 22 illustrates one  
 22 embodiment. Alternative embodiments for distributing the traffic messages are possible.

23 In an alternative embodiment, the central facility 26 directly broadcasts the traffic  
 24 messages 22. To broadcast the traffic messages, the central facility 26 includes  
 25 equipment and programming 20(3) that includes interfaces to transmitters, programming  
 26 that communicates formatted messages at regular intervals to the transmitters, and so on.

27  
 28 In another alternative embodiment, the traffic messages developed and  
 29 transmitted may include information other than the traffic and road condition  
 30 information. For example, the traffic messages may include weather related information  
 31 relevant to portions of the road network. It is intended that the foregoing detailed

1 description be regarded as illustrative rather than limiting and that it is understood that  
2 the following claims including all equivalents are intended to define the scope of the  
3 invention.
